Appl. No. 10/797,342

Amdt. dated August 12, 2005

Reply to Office action of May 12, 2005

Amendments to the Specification:

Please replace the paragraph [0005] beginning at page 2, with the following

rewritten paragraph:

[0005] It is a known practice to apply solid lubricant coatings such as silver

to the cages in rolling element bearings for some applications. The silver coatings on

the cages have two functions: (1) to form transfer films on the rolling elements and

raceways and (2) to provide a barrier to adhesive wear between the machined steel

cages and the land regions of the rings. An unanticipated but A prevalent problem with

this approach is that debris still present from the manufacturing process of the system,

ingested into the system during operation, or evolved in the system through normal

operation becomes trapped in the silver coating. Debris trapped in the silver coating is

especially harmful when it is located on the regions of the cage that contact the land

regions on the rings. The trapped debris behaves as grinding media and abrasively, or

adhesively (depending upon the debris type) wears material from the land surfaces.

When a critical amount of material has been removed from the land surface, the bearing

fails catastrophically.
